

# Assignment: AWS Application Load Balancer (ALB) with 3 Ubuntu EC2 Instances

## Objective

In this lab, students will deploy **three Ubuntu EC2 instances** running simple web applications, place them behind an **Application Load Balancer (ALB)**, and configure the environment so that the web application is accessible **only through the ALB DNS name**.

Each EC2 instance must display a **unique message** so that load balancing behavior can be verified from a web browser.

---

## Scenario

You are a Cloud Engineer responsible for deploying a highly available web application in AWS.

The application will run on three Ubuntu EC2 instances located behind an Application Load Balancer. When users access the ALB DNS name, traffic should be distributed across the three servers.

Each server must display a different message so that users can determine which server handled the request.

---

## Requirements

### Infrastructure Requirements

- 1 VPC
- 3 Ubuntu EC2 Instances
- 1 Target Group
- 1 Application Load Balancer (ALB)
- HTTP Protocol (Port 80)
- At least 2 Availability Zones
- Load balancing must be verified using the browser
